

COMP3301: Security

[Based on Chapter 15, OSC]

Security

- The Security Problem
- Program Threats
- System and Network Threats
- Cryptography as a Security Tool
- User Authentication
- Implementing Security Defenses

Objectives

- To discuss security threats and attacks
- To explain the fundamentals of encryption, authentication, and hashing
- To examine the uses of cryptography in computing
- To describe the various countermeasures to security attacks

The Security Problem

- System **secure** if resources used and accessed as intended under all circumstances
 - Unachievable
- **Intruders** (**crackers**) attempt to breach security
- **Threat** is potential security violation
- **Attack** is attempt to breach security
- Attack can be accidental or malicious
- Easier to protect against accidental than malicious misuse

Security Violation Categories

- ❑ **Breach of confidentiality**
 - ❑ Unauthorized reading of data
- ❑ **Breach of integrity**
 - ❑ Unauthorized modification of data
- ❑ **Breach of availability**
 - ❑ Unauthorized destruction of data
- ❑ **Theft of service**
 - ❑ Unauthorized use of resources
- ❑ **Denial of service (DOS)**
 - ❑ Prevention of legitimate use

Security Violation Methods

- **Masquerading** (breach **authentication**)
 - Pretending to be an authorized user to escalate privileges
- **Replay attack**
 - As is or with **message modification**
- **Man-in-the-middle attack**
 - Intruder sits in data flow, masquerading as sender to receiver and vice versa
- **Session hijacking**
 - Intercept an already-established session to bypass authentication

Security Measure Levels

- ❑ Impossible to have absolute security, but make cost to perpetrator sufficiently high to deter most intruders
- ❑ Security must occur at four levels to be effective:
 - ❑ **Physical**
 - ▶ Data centers, servers, connected terminals
 - ❑ **Human**
 - ▶ Avoid **social engineering**, **phishing**, **dumpster diving**
 - ❑ **Operating System**
 - ▶ Protection mechanisms, debugging
 - ❑ **Network**
 - ▶ Intercepted communications, interruption, DOS
- ❑ Security is as weak as the weakest link in the chain
- ❑ But can too much security be a problem?

Program Threats

- Many variations, many names
- **Trojan Horse**
 - Code segment that misuses its environment
 - Exploits mechanisms for allowing programs written by users to be executed by other users
 - **Spyware, pop-up browser windows, covert channels**
 - Up to 80% of spam delivered by spyware-infected systems
- **Trap Door**
 - Specific user identifier or password that circumvents normal security procedures
 - Could be included in a compiler
 - How to detect them?

Program Threats (Cont.)

- **Logic Bomb**

- Program that initiates a security incident under certain circumstances

- **Stack and Buffer Overflow**

- Exploits a bug in a program (overflow either the stack or memory buffers)
 - Failure to check bounds on inputs, arguments
 - Write past arguments on the stack into the return address on stack
 - When routine returns from call, returns to hacked address
 - ▶ Pointed to code loaded onto stack that executes malicious code
 - Unauthorized user or privilege escalation

Great Programming Required?

- For the first step of determining the bug, and second step of writing exploit code, yes
- **Script kiddies** can run pre-written exploit code to attack a given system
- Attack code can get a shell with the processes' owner's permissions
 - Or open a network port, delete files, download a program, etc
- Depending on bug, attack can be executed across a network using allowed connections, bypassing firewalls
- Buffer overflow can be disabled by disabling stack execution or adding bit to page table to indicate "non-executable" state
 - Available in SPARC and x86
 - But still have security exploits

Program Threats (Cont.)

□ Viruses

- Code fragment embedded in legitimate program
- Self-replicating, designed to infect other computers
- Very specific to CPU architecture, operating system, applications
- Usually borne via email or as a macro

The Threat Continues

- Attacks still common, still occurring
- Attacks moved over time from science experiments to tools of organized crime
 - Targeting specific companies
 - Creating botnets to use as tool for spam and DDOS delivery
 - **Keystroke logger** to grab passwords, credit card numbers
- Why is Windows the target for most attacks?
 - Most common
 - Everyone is an administrator
 - ▶ Licensing required?
 - **Monoculture** considered harmful

System and Network Threats

- Some systems “open” rather than **secure by default**
 - Reduce **attack surface**
 - But harder to use, more knowledge needed to administer
- Network threats harder to detect, prevent
 - Protection systems weaker
 - More difficult to have a shared secret on which to base access
 - No physical limits once system attached to internet
 - ▶ Or on network with system attached to internet
 - Even determining location of connecting system difficult
 - ▶ IP address is only knowledge

System and Network Threats (Cont.)

- **Worms** – use **spawn** mechanism; standalone program
- Internet worm
 - Exploited UNIX networking features (remote access) and bugs in *finger* and *sendmail* programs
 - Exploited trust-relationship mechanism used by *rsh* to access friendly systems without use of password
 - **Grappling hook** program uploaded main worm program
 - ▶ 99 lines of C code
 - Hooked system then uploaded main code, tried to attack connected systems
 - Also tried to break into other users accounts on local system via password guessing
 - If target system already infected, abort, except for every 7th time

System and Network Threats (Cont.)

□ Port scanning

- Automated attempt to connect to a range of ports on one or a range of IP addresses
- Detection of answering service protocol
- Detection of OS and version running on system
- `nmap` scans all ports in a given IP range for a response
- `nessus` has a database of protocols and bugs (and exploits) to apply against a system
- Frequently launched from **zombie systems**
 - ▶ To decrease trace-ability

System and Network Threats (Cont.)

□ Denial of Service

- Overload the targeted computer preventing it from doing any useful work
- **Distributed denial-of-service (DDOS)** come from multiple sites at once
- Consider the start of the IP-connection handshake (SYN)
 - ▶ How many started-connections can the OS handle?
- Consider traffic to a web site
 - ▶ How can you tell the difference between being a target and being really popular?
- Accidental – CS students writing bad `fork()` code
- Purposeful – extortion, punishment

Cryptography

- Means to constrain potential senders (*sources*) and / or receivers (*destinations*) of *messages*
 - Based on secrets (**keys**)
 - Enables
 - ▶ Confidentiality
 - ▶ Confirmation of source
 - ▶ Receipt only by certain destination
 - ▶ Trust relationship between sender and receiver

Authentication

- Constraining set of potential senders of a message
 - Complementary to encryption
 - Also can prove message unmodified
- Digital Signatures
 - Based on asymmetric keys and digital signature algorithm
 - Authenticators produced are **digital signatures**
 - Very useful – **anyone** can verify authenticity of a message

Authentication – Digital Signature

- Based on asymmetric keys and digital signature algorithm
- Authenticators produced are **digital signatures**
- Very useful – ***anyone*** can verify authenticity of a message

?

Key Distribution

- Delivery of symmetric key is huge challenge
 - Sometimes done **out-of-band**
- Asymmetric keys can proliferate – stored on **key ring**
 - Even asymmetric key distribution needs care – man-in-the-middle attack

Digital Certificates

- Proof of who or what owns a public key
- Public key digitally signed a trusted party
- Trusted party receives proof of identification from entity and certifies that public key belongs to entity
- **Certificate authority** are trusted party – their public keys included with web browser distributions
 - They vouch for other authorities via digitally signing their keys, and so on

User Authentication

- ❑ Crucial to identify user correctly, as protection systems depend on user ID
- ❑ User identity most often established through **passwords**, can be considered a special case of either keys or capabilities
- ❑ Passwords must be kept secret
 - ❑ Frequent change of passwords
 - ❑ History to avoid repeats
 - ❑ Use of “non-guessable” passwords
 - ❑ Log all invalid access attempts (but not the passwords themselves)
 - ❑ Unauthorized transfer
- ❑ Passwords may also either be encrypted or allowed to be used only once
 - ❑ Does encrypting passwords solve the exposure problem?
 - ▶ Might solve **sniffing**
 - ▶ Consider **shoulder surfing**
 - ▶ Consider Trojan horse keystroke logger
 - ▶ How are passwords stored at authenticating site?

Passwords

- Encrypt to avoid having to keep secret
 - But keep secret anyway (i.e. Unix uses superuser-only readable file `/etc/shadow`)
 - Use algorithm easy to compute but difficult to invert
 - Only encrypted password stored, never decrypted
 - Add “salt” to avoid the same password being encrypted to the same value
- One-time passwords
 - Use a function based on a seed to compute a password, both user and computer
 - Hardware device / calculator / key fob to generate the password
 - ▶ Changes very frequently
- Biometrics
 - Some physical attribute (fingerprint, hand scan)
- Multi-factor authentication
 - Need two or more factors for authentication
 - ▶ i.e. USB “dongle”, biometric measure, and password

Implementing Security Defenses

- **Defense in depth** is most common security theory – multiple layers of security
- **Security policy** describes what is being secured
- Vulnerability assessment compares real state of system / network compared to security policy
- Intrusion detection endeavors to detect attempted or successful intrusions
 - **Signature-based** detection spots known bad patterns
 - **Anomaly detection** spots differences from normal behavior
 - ▶ Can detect **zero-day** attacks
 - **False-positives** and **false-negatives** a problem
- Virus protection
 - Searching all programs or programs at execution for known virus patterns
 - Or run in **sandbox** so can't damage system
- Auditing, accounting, and logging of all or specific system or network activities
- Practice **safe computing** – avoid sources of infection, download from only “good” sites, etc

Questions?
